

11.x — Chapter 11 summary and quiz

👤 [ALEX¹](#) ⌚ **SEPTEMBER 28, 2024**

Nice work. Function templates may seem pretty complex, but they are a very powerful way to make your code work with objects of different types. We'll see a lot more template stuff in future chapters, so hold on to your hat.

Chapter Review

Function overloading allows us to create multiple functions with the same name, so long as each identically named function has different set of parameter types (or the functions can be otherwise differentiated). Such a function is called an **overloaded function** (or **overload** for short). Return types are not considered for differentiation.

When resolving overloaded functions, if an exact match isn't found, the compiler will favor overloaded functions that can be matched via numeric promotions over those that require numeric conversions. When a function call is made to function that has been overloaded, the compiler will try to match the function call to the appropriate overload based on the arguments used in the function call. This is called **overload resolution**.

An **ambiguous match** occurs when the compiler finds two or more functions that can match a function call to an overloaded function and can't determine which one is best.

A **default argument** is a default value provided for a function parameter. Parameters with default arguments must always be the rightmost parameters, and they are not used to differentiate functions when resolving overloaded functions.

Function templates allow us to create a function-like definition that serves as a pattern for creating related functions. In a function template, we use **type template parameters** as placeholders for any types we want to be specified later. The syntax that tells the compiler we're defining a template and declares the template types is called a **template parameter declaration**.

The process of creating functions (with specific types) from function templates (with template types) is called **function template instantiation** (or **instantiation**) for short. When this process happens due to a function call, it's called **implicit instantiation**. An instantiated function is called a **function instance** (or **instance** for short, or sometimes a **template function**).

Template argument deduction allows the compiler to deduce the actual type that should be used to instantiate a function from the arguments of the function call. Template argument deduction does not do type conversion.

Template types are sometimes called **generic types**, and programming using templates is sometimes called **generic programming**.

In C++20, when the `auto` keyword is used as a parameter type in a normal function, the compiler will automatically convert the function into a function template with each `auto` parameter becoming an

independent template type parameter. This method for creating a function template is called an **abbreviated function template**.

A **non-type template parameter** is a template parameter with a fixed type that serves as a placeholder for a constexpr value passed in as a template argument.

Quiz time

Question #1

1a) What is the output of this program and why?

```
1  #include <iostream>
2
3  void print(int x)
4  {
5      std::cout << "int " << x << '\n';
6  }
7
8  void print(double x)
9  {
10     std::cout << "double " << x << '\n';
11 }
12
13 int main()
14 {
15     short s { 5 };
16     print(s);
17
18     return 0;
19 }
```

[Show Solution \(javascript:void\(0\)\)²](#)

1b) Why won't the following compile?

```
1  #include <iostream>
2
3  void print()
4  {
5      std::cout << "void\n";
6  }
7
8  void print(int x=0)
9  {
10     std::cout << "int " << x << '\n';
11 }
12
13 void print(double x)
14 {
15     std::cout << "double " << x << '\n';
16 }
17
18 int main()
19 {
20     print(5.0f);
21     print();
22
23     return 0;
24 }
```

[Show Solution \(javascript:void\(0\)\)²](#)

1c) Why won't the following compile?

```
1 | #include <iostream>
2 |
3 | void print(long x)
4 | {
5 |     std::cout << "long " << x << '\n';
6 | }
7 |
8 | void print(double x)
9 | {
10 |    std::cout << "double " << x << '\n';
11 | }
12 |
13 | int main()
14 | {
15 |     print(5);
16 |
17 |     return 0;
18 | }
```

[Show Solution](#) (javascript:void(0))²

Question #2

> Step #1

Write a function template named `add()` that allows the users to add 2 values of the same type. The following program should run:

```
1 | #include <iostream>
2 |
3 | // write your add function template here
4 |
5 | int main()
6 | {
7 |     std::cout << add(2, 3) << '\n';
8 |     std::cout << add(1.2, 3.4) << '\n';
9 |
10 |    return 0;
11 | }
```

and produce the following output:

```
5
4.6
```

[Show Solution](#) (javascript:void(0))²

> Step #2

Write a function template named `mult()` that allows the user to multiply one value of any type (first parameter) and an integer (second parameter). The second parameter should not be a template type. The function should return the same type as the first parameter. The following program should run:

```

1  #include <iostream>
2
3  // write your mult function template here
4
5  int main()
6  {
7      std::cout << mult(2, 3) << '\n';
8      std::cout << mult(1.2, 3) << '\n';
9
10     return 0;
11 }

```

and produce the following output:

```

6
3.6

```

[Show Solution](#) (javascript:void(0))²

> Step #3

Write a function template named `sub()` that allows the user to subtract two values of different types. The following program should run:

```

1  #include <iostream>
2
3  // write your sub function template here
4
5  int main()
6  {
7      std::cout << sub(3, 2) << '\n';
8      std::cout << sub(3.5, 2) << '\n';
9      std::cout << sub(4, 1.5) << '\n';
10
11     return 0;
12 }

```

and produce the following output:

```

1
1.5
2.5

```

[Show Solution](#) (javascript:void(0))²

Question #3

What is the output of this program and why?

```

1  #include <iostream>
2
3  template <typename T>
4  int count(T) // This is the same as int count(T x), except we're not giving the
   parameter a name since we don't use the parameter
5  {
6      static int c { 0 };
7      return ++c;
8  }
9
10 int main()
11 {
12     std::cout << count(1) << '\n';
13     std::cout << count(1) << '\n';
14     std::cout << count(2.3) << '\n';
15     std::cout << count<double>(1) << '\n';
16
17     return 0;
18 }

```

[Show Solution \(javascript:void\(0\)\)](#)²

Question #4

What is the output of this program?

```

1  #include <iostream>
2
3  int foo(int n)
4  {
5      return n + 10;
6  }
7
8  template <typename T>
9  int foo(T n)
10 {
11     return n;
12 }
13
14 int main()
15 {
16     std::cout << foo(1) << '\n'; // #1
17
18     short s { 2 };
19     std::cout << foo(s) << '\n'; // #2
20
21     std::cout << foo<int>(4) << '\n'; // #3
22
23     std::cout << foo<int>(s) << '\n'; // #4
24
25     std::cout << foo<>(6) << '\n'; // #5
26
27     return 0;
28 }

```

Question #4

Got a couple wrong, because I thought the compiler would always prefer a non-template function when given the choice.

11

12 - thought compiler would prefer non-template version

4

2

16 - thought compiler would prefer non-template version

Question #2

Step 1:

```
1  #include <iostream>
2
3  template <typename T>
4  T add(T firstNumber, T secondNumber)
5  {
6      return firstNumber + secondNumber;
7  }
8
9  int main()
10 {
11     std::cout << add(2, 3) << '\n';
12     std::cout << add(1.2, 3.4) << '\n';
13
14     return 0;
15 }
```

Step 2:

```

1  #include <iostream>
2
3  template <typename T>
4  T mult(T firstNumber, int secondNumber)
5  {
6      return firstNumber * secondNumber;
7  }
8
9  int main()
10 {
11     std::cout << mult(2, 3) << '\n';
12     std::cout << mult(1.2, 3) << '\n';
13
14     return 0;
15 }

```

Step 3:

```

1  #include <iostream>
2
3  template <typename T, typename U>
4  auto sub(T firstNumber, U secondNumber)
5  {
6      return firstNumber - secondNumber;
7  }
8
9  int main()
10 {
11     std::cout << sub(3, 2) << '\n';
12     std::cout << sub(3.5, 2) << '\n';
13     std::cout << sub(4, 1.5) << '\n';
14
15     return 0;
16 }

```

Question #1

- a: int 5, short s gets promoted to an int.
- b: ambiguous match
- c: ambiguous match, both are conversions

Hey Alex, I just wanted to say that I've really been enjoying learning C++ from you! it's been a great learning experience. That said, I sometimes feel like I'm not practicing enough. Could you recommend some good places to find practice projects or exercises? I don't want to just read , I want to apply what I'm learning. Thanks :D

Hi Alex! I've been working through these tutorials since last August. I know C++ is a very broad language and it's not possible to cover everything, but have you gone over/are you planning to go over variadic templates? What is a good place to study them considering I already read chapter 11 and I'm currently going over chapter 27?

P.S.: Thank you so much for these tutorials! I was afraid of learning C++ and I stumbled upon this website while reading about learning C++ in reddit. It's a very complete and in-depth tutorial/guide and I'm sure everyone who uses these free learning resources is as thankful as me.

At some point I will cover them. But I doubt soon. There are so many other topics of interest and areas of higher use that need improvement. I can't advise on where the best place to study them is, as I haven't done a lot of research yet.

i know that u said you cant tell us the best place to study them yet, but do you feel like after completing the series, other than practice we would need to cover other topics in c++ (other than dsa) to pursue a career in it? By career i mean like becoming a developer or going into competitive programming and all

What exactly do the empty brackets `<>` mean in the context of templates? I've also noticed them when you type out the code that gets generated by the compiler when functions for a specific type are instantiated.

For Step 3 for subtraction Would this code also work

```
1 | #include <iostream>
2 |
3 | // write your sub function template here
4 | template <typename T>
5 | T sub(T x, T y) {
6 |
7 |     return x - y;
8 | }
9 |
10 | int main()
11 | {
12 |     std::cout << sub(3, 2) << '\n';
13 |     std::cout << sub<double>(3.5, 2) << '\n';
14 |     std::cout << sub<double>(4, 1.5) << '\n';
15 |
16 |     return 0;
17 | }
```

🗨 Reply to [Jaximus Prime](#)¹⁴ 🕒 December 31, 2024 6:36 pm PST

Hello. I am also learning, so don't quote me on this.

Anyways, your code does work, but it doesn't solve the question the author had asked. After you wrote your code, you were supposed to run it with the given function calls meant to be pasted in main():

```
1 | int main() {
2 |     std::cout << sub(3, 2) << '\n';
3 |     std::cout << sub(3.5, 2) << '\n';
4 |     std::cout << sub(4, 1.5) << '\n';
5 | }
```

Furthermore, the question also asks you to create code that "allows the user to subtract two values of different types," essentially asking you to create two typenames in the template. Your code only allows for one (although two through type conversions) because there is only one `typename` in the template, thus allowing for only one type substitution.

Overall, your code does work, but you didn't solve it the way the author intended to.
